

## Run plan

1. a) With PMT in place measure  $\Delta t$  of attenuated beam.
- b) at  $\approx 550 \frac{\text{keV}}{\text{n}}$   $^{13}\text{C}$   
 $\Delta t = 3.4 \pm 0.7 \text{ nsec}$   
    ↑ kick from  $\delta$  ( $\approx 5.7 \text{ MeV}$ )
  - see if we can separate beam/recoils
  - want to put timing through a TAC and into one of the ADC's - I will look into this
2. Put DSSSD in to get an  $E$  signal
  - also would like to get  $t$  signal into ADC via TAC.
    - $m = \text{const. } Et^2$ 
      - should be able to get const from previous tests ( $^{20}\text{Ne}$ , I think) would give 2 points for measurement of const. ( $^{13}\text{C}$  the other)

- from MCP to DSSSD  $\ell \approx 60\text{ cm}$ , if we get 1.5 nsec ~~time~~ and  $\Delta E = 2\%$ .

$$\frac{\Delta m}{m} \approx \frac{1}{18}$$

(Is  $\ell = 60\text{ cm}$  if timing blur)  
MCP and RF?

$\Rightarrow$  would be able to separate  $^{13}\text{C}$  from  $^{14}\text{N}$

- Problem?  $E$  and  $t$  correlated if I use buncher. Would have to see which term dominates.

$\rightarrow$  do  $E t^2$  analysis of beam and records
